

ENSO Cycle: Recent Evolution, Current Status and Predictions

Update prepared by Climate Prediction Center / NCEP 11 October 2011

Outline

- Overview
- Recent Evolution and Current Conditions
- Oceanic Niño Index (ONI) "Revised December 2008"
- Pacific SST Outlook
- U.S. Seasonal Precipitation and Temperature Outlooks
- Summary
- La Niña Composites

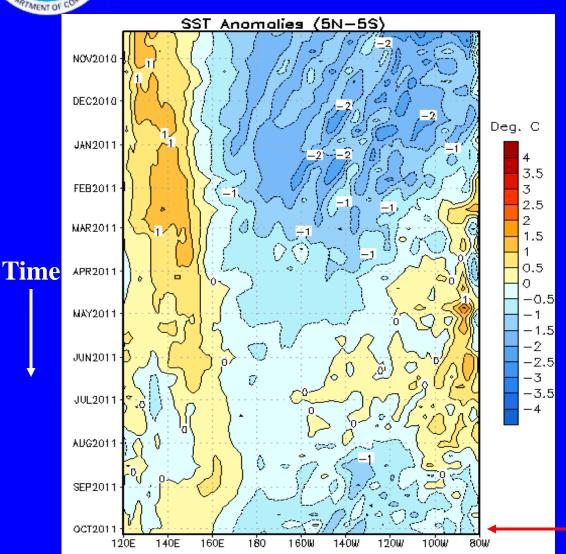

Summary

- La Niña conditions are present across the equatorial Pacific.*
- Sea surface temperature (SST) anomalies have become increasingly negative in the east-central equatorial Pacific Ocean.
- Atmospheric circulation anomalies are consistent with La Niña.
- La Niña is expected to strengthen and continue through the Northern Hemisphere winter 2011-12.*

* Note: These statements are updated once a month in association with the ENSO Diagnostics Discussion: http://www.cpc.ncep.noaa.gov/products/analysis_monitoring/enso_advisory

Recent Evolution of Equatorial Pacific SST Departures (°C)

Since early August 2011, negative SST anomalies have gradually strengthened across much of the equatorial Pacific.

Longitude

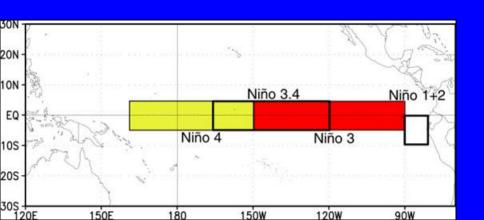

Niño 1+2

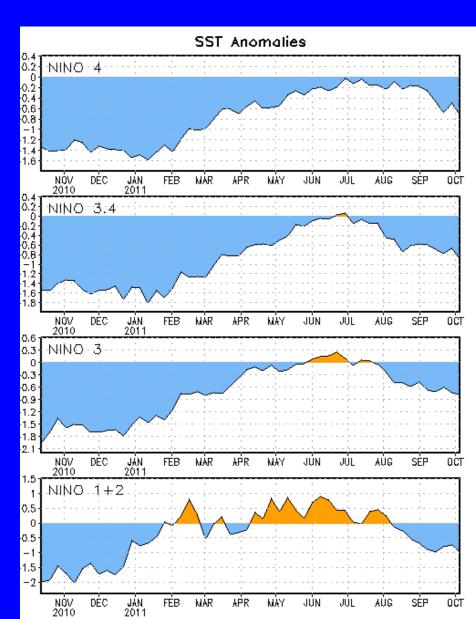

Niño Region SST Departures (°C) Recent Evolution

The latest weekly SST departures are:

Niño 4 -0.7°C Niño 3.4 -0.9°C Niño 3 -0.8°C

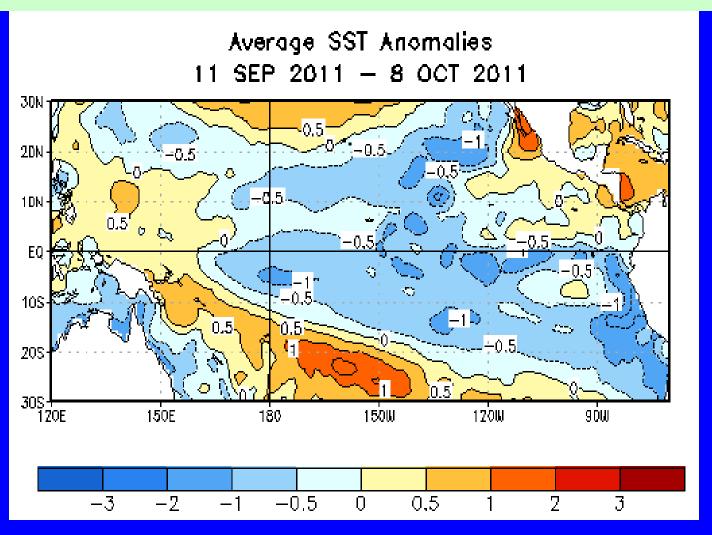

-1.0°C

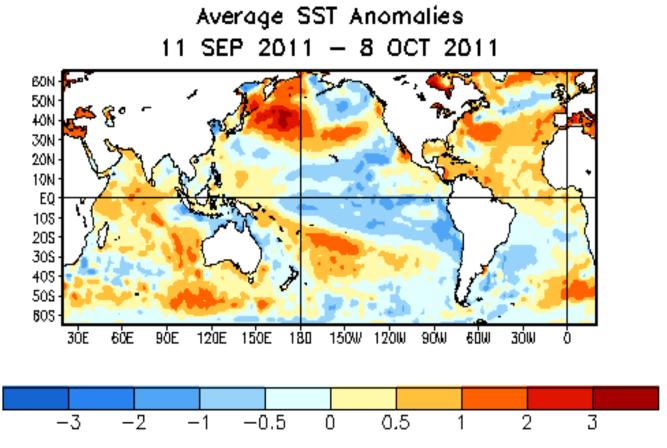

SST Departures (°C) in the Tropical Pacific During the Last 4 Weeks

During the last 4-weeks, equatorial SSTs were more than 0.5°C below average east of 170°E.

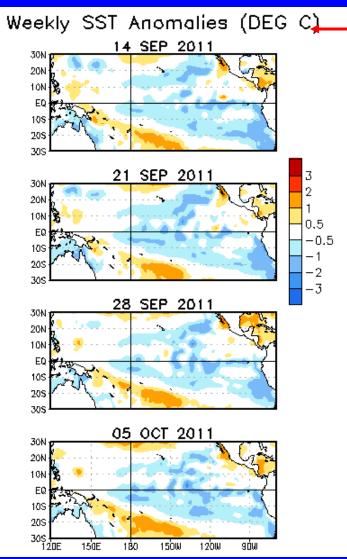

Global SST Departures (°C)

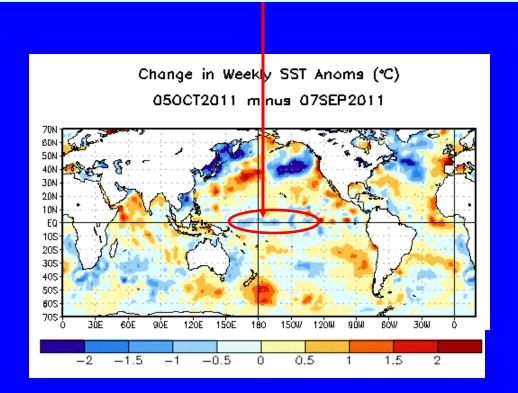

During the last four weeks, equatorial SSTs were below average across much of the Pacific Ocean and above average across much of the Indian Ocean. A horseshoe pattern of above-average SSTs extended from the Maritime Continent into the middle latitudes of the Pacific Ocean.

Weekly SST Departures (°C) for the Last Four Weeks

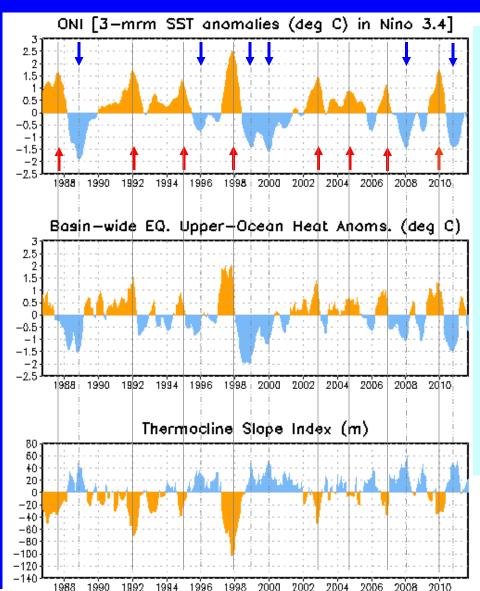

- During the last four weeks, equatorial SSTs were below average across most of the Pacific.
- During the last 30 days, equatorial SST anomalies decreased in the central and east-central Pacific.

Upper-Ocean Conditions in the Eq. Pacific

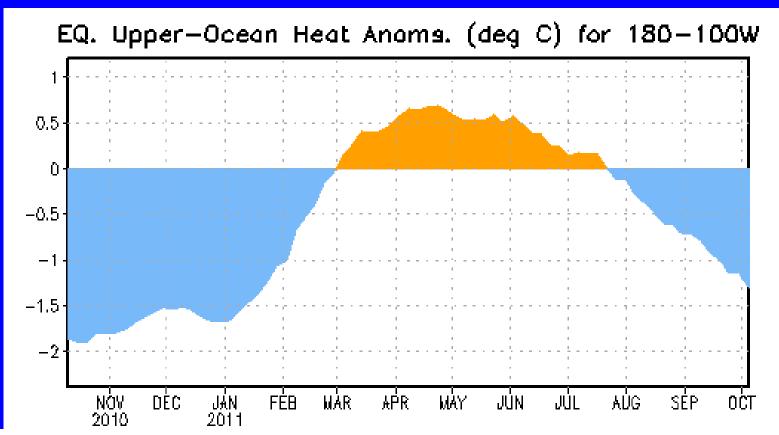

- The basin-wide equatorial upper ocean (0-300 m) heat content is greatest prior to and during the early stages of a Pacific warm (El Niño) episode (compare top 2 panels) and least prior to and during the early stages of a cold (La Niña) episode.
- The slope of the oceanic thermocline is least (greatest) during warm (cold) episodes.
- Recent values of the upperocean heat anomalies (negative) and a positive thermocline slope index reflect La Niña conditions.

The monthly thermocline slope index represents the difference in anomalous depth of the 20°C isotherm between the western Pacific (160°E-150°W) and the eastern Pacific (90°-140°W).

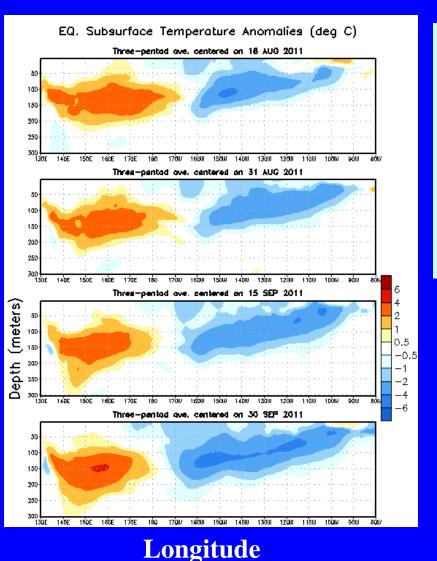

Weekly Central & Eastern Pacific Upper-Ocean (0-300 m) Average Temperature Anomalies

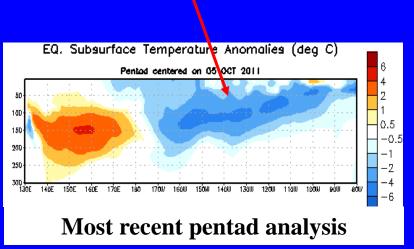

In January 2011 the negative anomalies began to decrease in magnitude, with positive anomalies evident from March-July 2011. Since late July 2011, temperature anomalies have become increasingly negative.

Sub-Surface Temperature Departures (°C) in the Equatorial Pacific

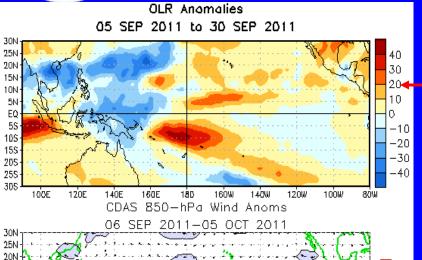

- Since mid August 2011, positive subsurface temperature anomalies (100-300m) have been observed in the western Pacific Ocean. Negative anomalies in the east-central Pacific have strengthened and expanded eastward.
- In the recent period, the negative subsurface anomalies continued to strengthen.

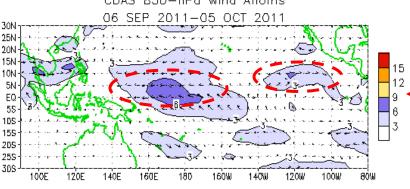

Time

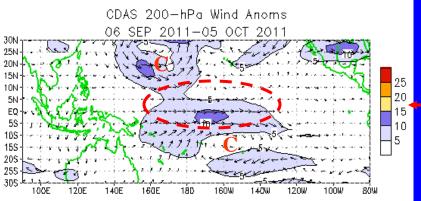

Tropical OLR and Wind Anomalies During the Last 30 Days

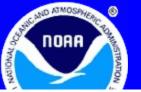

Negative OLR anomalies (enhanced convection and precipitation, blue shading) were located over the western tropical Pacific. Positive OLR anomalies (suppressed convection and precipitation, red shading) were located near the Date Line.

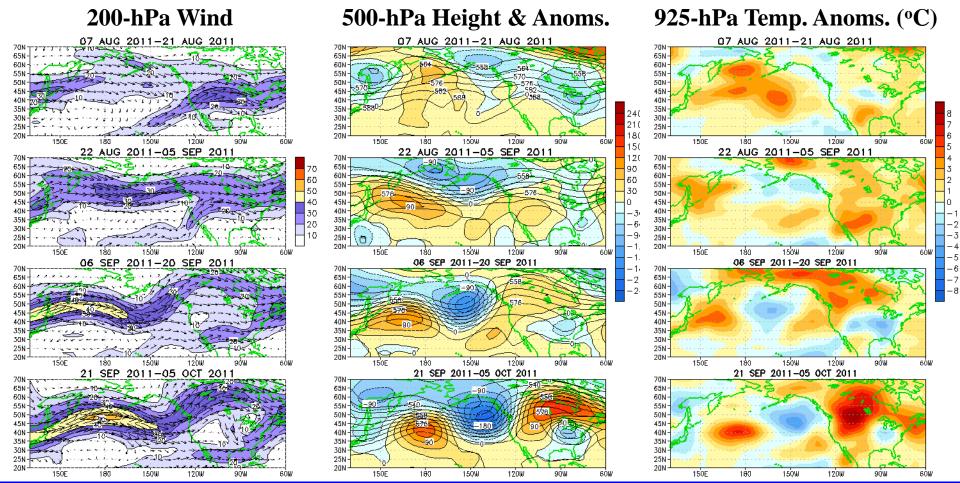

Low-level (850-hPa) easterly anomalies were observed over the central tropical Pacific. Anomalous westerlies were evident across the eastern tropical Pacific, centered north of the equator.

Upper-level (200-hPa) westerly anomalies were observed over the central Pacific. Anomalous cyclonic circulation centers were present in the subtropics of both hemispheres

Atmospheric Circulation over the North Pacific & North America During the Last 60 Days

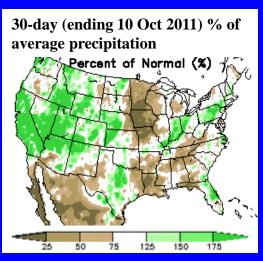

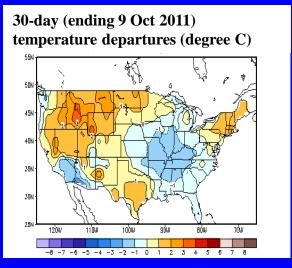

From late August through early October, 500-hPa heights were above-average over western N. America and below-average over the eastern U.S. Since the beginning of September, below-average temperatures are evident over portions of the central and southeastern U.S., while the western U.S. has experienced above-average temperatures.

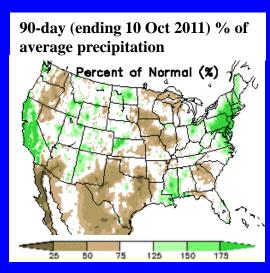

U.S. Temperature and Precipitation Departures During the Last 30 and 90 Days

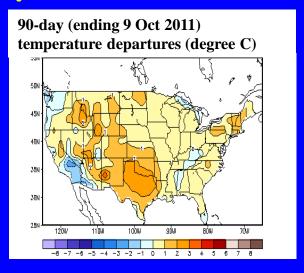

Last 30 Days

Last 90 Days

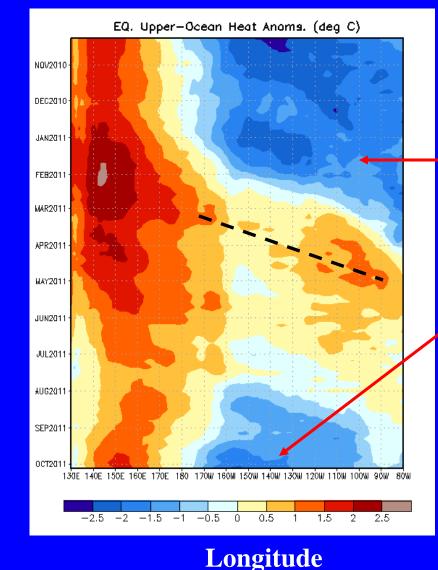

Intraseasonal Variability

- Intraseasonal variability in the atmosphere (wind and pressure), which is often related to the Madden-Julian Oscillation (MJO), can significantly impact surface and subsurface conditions across the Pacific Ocean.
- Related to this activity
 - significant weakening of the low-level easterly winds usually initiates an eastward-propagating oceanic Kelvin wave.

Weekly Heat Content Evolution in the Equatorial Pacific

• Oceanic Kelvin waves have alternating warm and cold phases. The warm phase is indicated by dashed lines. Down-welling and warming occur in the leading portion of a Kelvin wave, and up-

welling and cooling occur in the trailing portion.

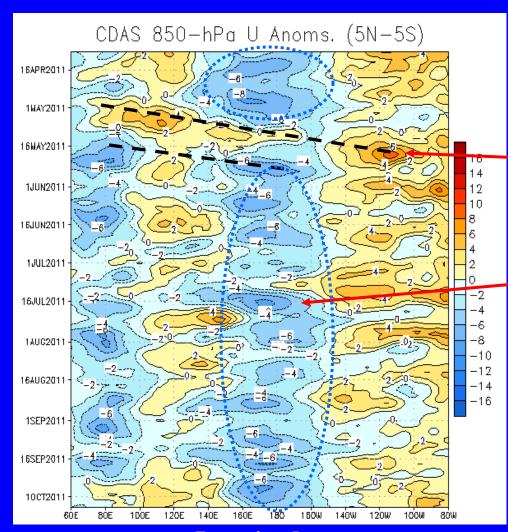

- From May 2010- January 2011, negative heat content anomalies extended across the equatorial Pacific in association with La Niña.
- From February-June 2011, the heat content was above-average, especially across the western Pacific.
- Since late July 2011, negative heat content anomalies have strengthened in the central and eastern equatorial Pacific.

Time

Low-level (850-hPa) Zonal (east-west) Wind Anomalies (m s⁻¹)

Westerly wind anomalies (orange/red shading).

Easterly wind anomalies (blue shading).

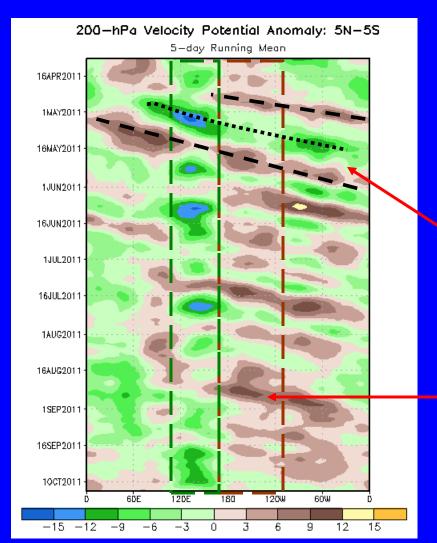

During May 2011, the MJO contributed to increased variability across the western and central Pacific Ocean.

Since March 2010, low-level easterly wind anomalies have persisted over the western and central equatorial Pacific.

Longitude

200-hPa Velocity Potential Anomalies (5°N-5°S)

Positive anomalies (brown shading) indicate unfavorable conditions for precipitation.

Negative anomalies (green shading) indicate favorable conditions for precipitation.

During May 2011, the eastward shift of the velocity potential anomalies reflected the M.IO.

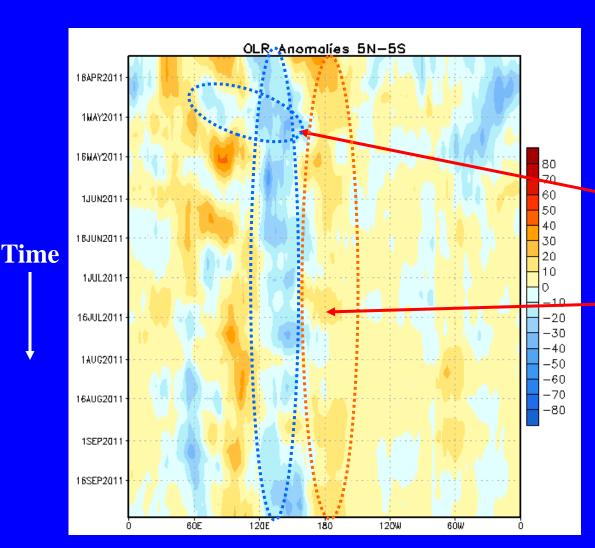

Since May 2010, persistent upper-level convergence anomalies (brown) were evident over the central Pacific, while anomalous upper-level divergence (green) generally prevailed over the Maritime Continent.

Time

Longitude

Outgoing Longwave Radiation (OLR) Anomalies

Drier-than-average conditions (orange/red shading) Wetter-than-average conditions (blue shading)

The eastward shift of negative OLR anomalies from the Indian Ocean to the western Pacific is consistent with the M.IO.

Since April 2010, negative OLR anomalies have been observed near the Maritime Continent and positive OLR anomalies have prevailed over the western and central Pacific.

Longitude

Oceanic Niño Index (ONI)

- The ONI is based on SST departures from average in the Niño 3.4 region, and is a principal measure for monitoring, assessing, and predicting ENSO.
- <u>Defined as the three-month running-mean SST departures</u> in the Niño 3.4 region. Departures are based on a set of improved homogeneous historical SST analyses (Extended Reconstructed SST <u>ERSST.v3b</u>). The SST reconstruction methodology is described in Smith et al., 2008, *J. Climate*, vol. 21, 2283-2296.)
- Used to place current events into a historical perspective
- NOAA's operational definitions of El Niño and La Niña are keyed to the ONI index.

NOAA Operational Definitions for El Niño and La Niña

El Niño: characterized by a *positive* ONI greater than or equal to +0.5°C.

La Niña: characterized by a *negative* ONI less than or equal to -0.5°C.

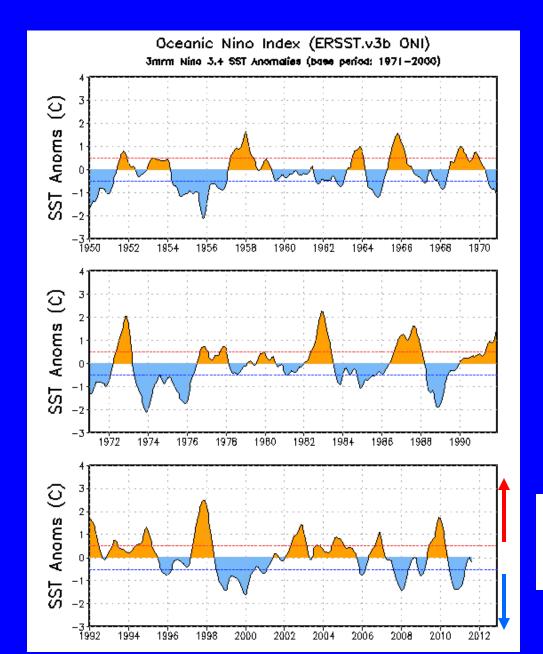

By historical standards, to be classified as a full-fledged El Niño or La Niña <u>episode</u>, these thresholds must be exceeded for a period of at least 5 consecutive overlapping 3-month seasons.

CPC considers El Niño or La Niña <u>conditions</u> to occur when the monthly Niño3.4 OISST departures meet or exceed +/- 0.5°C along with consistent atmospheric features. These anomalies must also be forecasted to persist for 3 consecutive months.

ONI (°C): Evolution since 1950

The most recent ONI value (July – September 2011) is -0.2°C.

El Niño neutral La Niña

Historical El Niño and La Niña Episodes

Based on the ONI computed using ERSST.v3b

NOTE:

After updating the ocean analysis to ERSST.v3b, a new La Niña episode was classified (ASO 1962-DJF 1962/63) and two previous La Niña episodes were combined into one single episode (AMJ 1973- MAM 1976).

Lowest

Historical Pacific warm (red) and cold (blue) episodes based on a threshold of +/- 0.5 °C for the Oceanic Nino Index (ONI) [3 month running mean of ERSST.v3b SST anomalies in the Nino 3.4 region (5N-5S, 120-170W)], calculated with respect to the 1971-2000 base period. For historical purposes El Niño and La Niña episodes are defined when the threshold is met for a minimum of 5 consecutive over-lapping seasons.

Pacific Niño 3.4 SST Outlook

• An increasing number of ENSO models predict the continuation of La Niña into the Northern Hemisphere winter (Niño-3.4 SST anomalies less than -0.5°C).

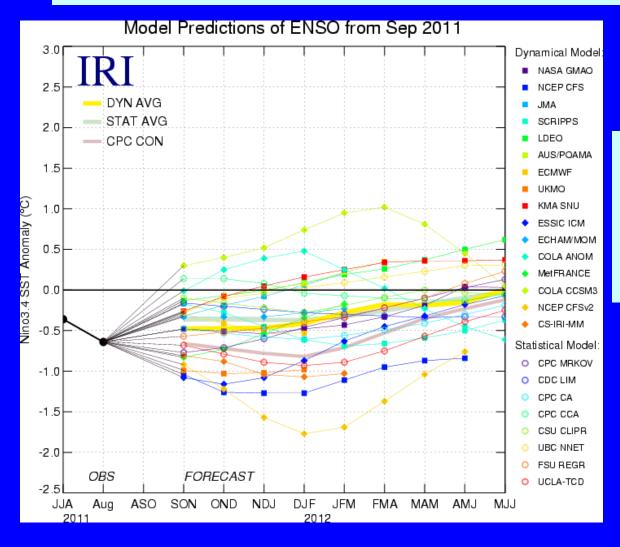

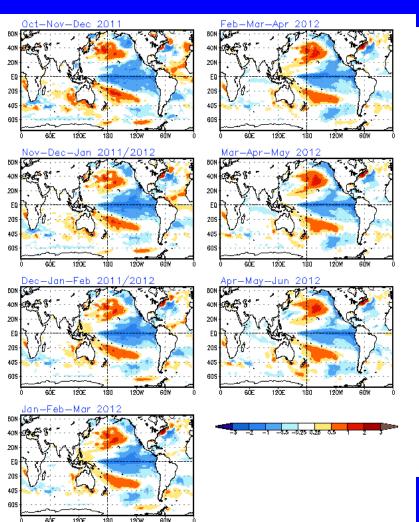

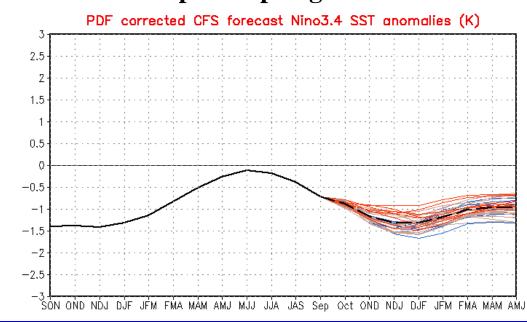

Figure provided by the International Research Institute (IRI) for Climate and Society (updated 13 September 2011).

SST Outlook: NCEP <u>CFS.v1</u> Forecast Issued 10 October 2011

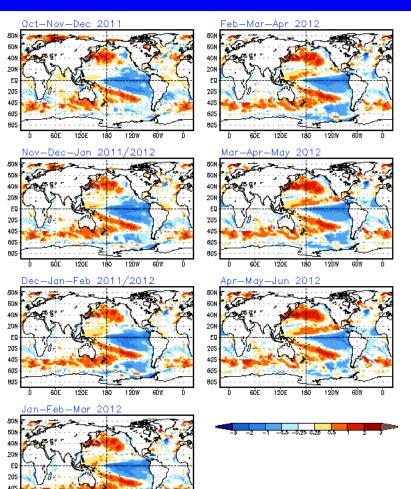

The CFS.v1 ensemble mean (black dashed line) predicts La Niña conditions to strengthen and continue through the Northern Hemisphere spring 2012.

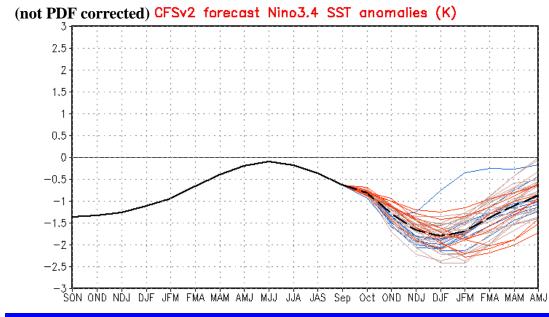

SST Outlook: NCEP <u>CFS.v2</u> Forecast Issued 11 October 2011

The CFS.v2 ensemble mean (black dashed line) predicts La Niña conditions to strengthen and continue into the Northern Hemisphere spring 2012.

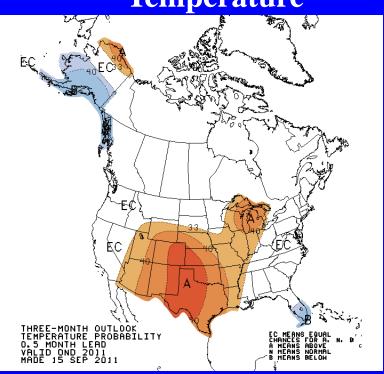

CFS.v2 is now operational. More information on version 2 is available at http://cfs.ncep.noaa.gov/cfsv2/docs.html

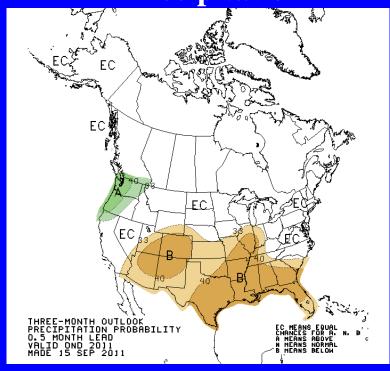

U. S. Seasonal Outlooks October – December 2011

Temperature

Precipitation

The seasonal outlooks combine the effects of long-term trends, soil moisture, and, when appropriate, ENSO.

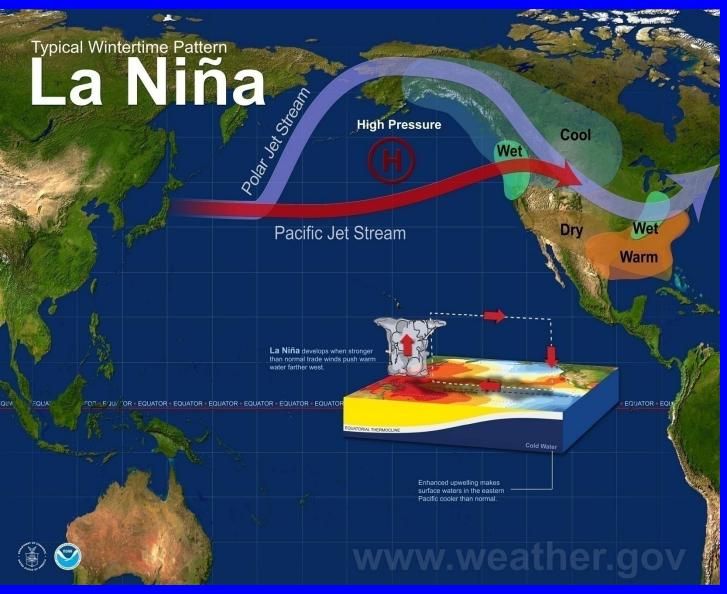

Summary

- La Niña conditions are present across the equatorial Pacific.*
- Sea surface temperature (SST) anomalies have become increasingly negative in the east-central equatorial Pacific Ocean.
- Atmospheric circulation anomalies are consistent with La Niña.
- La Niña is expected to strengthen and continue through the Northern Hemisphere winter 2011-12.*

* Note: These statements are updated once a month in association with the ENSO Diagnostics Discussion: http://www.cpc.ncep.noaa.gov/products/analysis_monitoring/enso_advisory

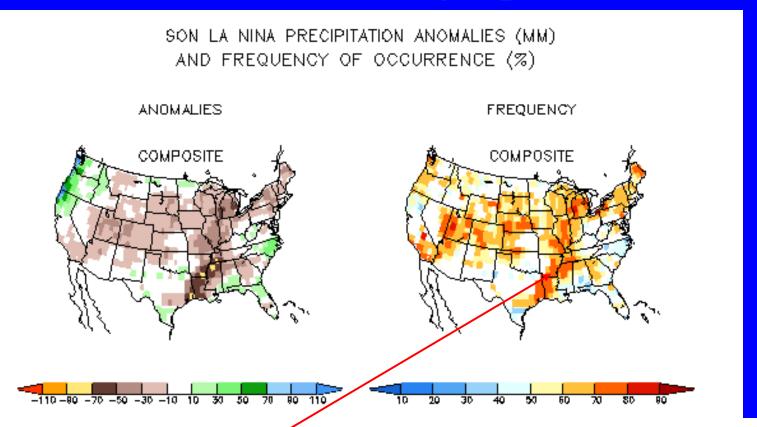

Typical US Temperature, Precipitation and Jet Stream Patterns during La Niña Winters

U.S. Precipitation Departures (mm) and Frequency of Occurrence (%) for La Niña during Sep.-Nov.

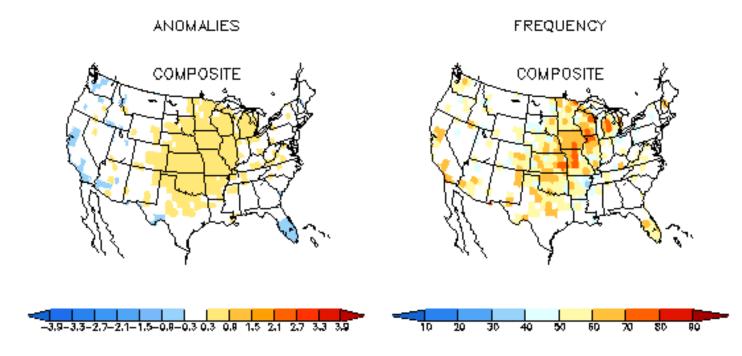

(19 CASES: 1950 1954 1955 1956 1962 1964 1970 1971 1973 1974 1975 1984 1988 1995 1998 1999 2000 2007 2010)

FREQUENCY (right panel) indicates the percentage of La Niña years that the indicated departure (left panel) occurred. For example, below-average seasonal precipitation over the Mississippi Valley occurred in 70%-80% of the La Niña years.
